Chapter 2

Introduction to Data Science

Instructor: Yared Sirak
B.sc Information System
M.sc Software Engineering

Outline

- Overview for Data Science
  - Definition of data and information
  - Data types and representation
- Data Value Chain
  - Data Acquisition
  - Data Analysis
  - Data Curating
  - Data Storage
  - Data Usage
- Basic concepts of Big data

Overview of Data Science

- Data science is a multi-disciplinary field that uses scientific methods, processes, algorithms and systems to extract knowledge and insights from structured, semi structured and unstructured data.
- Data science continues to evolve as one of the most promising and in-demand career paths for skilled professionals.
- Today, successful data professionals understand that they must advance past traditional skills of analyzing large amounts of data, data mining, and programming skills.

Overview of Data Science

- In order to uncover useful intelligence for their organizations, data scientists must master the full spectrum of the data science life cycle and possess a level of flexibility and understanding to maximize returns at each phase of the process.
- Data scientists need to be curious and result-oriented, with exceptional industry-specific knowledge and communication skills that allow them to explain highly technical results to their non-technical counterparts.
- Data science need a strong quantitative background in statistics and linear algebra as well as programming knowledge with focuses in data warehousing, mining, and modeling to build and analyze algorithms.

Definition of Data and Information

What is data?

- Data can be defined as a representation of facts, concepts, or instructions in a formalized manner, which should be suitable for communication, interpretation, or processing by human or electronic machine.
- Data is represented with the help of characters such as alphabets (A-Z, a-z), digits (0-9) or special characters (+,-,/,*,<,>,= etc.)

What is Information?

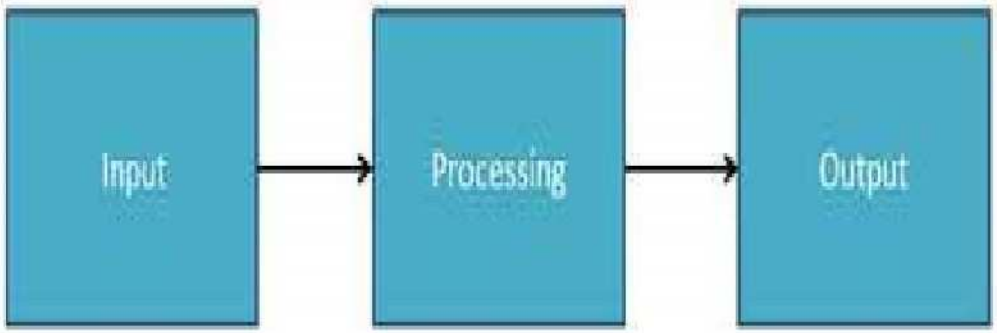
- Information is organized or classified data, which has some meaningful values for the receiver.
- Information is the processed data on which decisions and actions are based.
- Information is a data that has been processed into a form that is meaningful to recipient and is of real or perceived value in the current or the prospective action or decision of recipient.
- For the decision to be meaningful, the processed data must qualify for the following characteristics −
  - Timely − Information should be available when required.
  - Accuracy − Information should be accurate.
  - Completeness − Information should be complete.

Data Vs. Information

Data	Information
Described as unprocessed or raw facts and figures	Described as processed data
Cannot help in decision making	Can help in decision making
Raw material that can be organized, structured, and interpreted to create useful information systems.	Interpreted data; created from organized, structured, and processed data in a particular context.
'groups of non-random' symbols in the form of text, images, and voice representing quantities, action and objects'.	Processed data in the form of text, images, and voice representing quantities, action and objects'.

Data Processing Cycle

- Data processing is the re-structuring or re-ordering of data by people or machine to increase their usefulness and add values for a particular purpose.
- Data processing consists of the following basic steps - input, processing, and output. These three steps constitute the data processing cycle.



Data Processing Cycle

- **Input step** – the input data is prepared in some convenient form for processing. The form depends on the processing machine.
  - For example - when electronic computers are used, the input data can be recorded on any one of the several types of input medium, such as magnetic disks, tapes,
- **Processing step** – the input data is changed to produce dat in a more useful form.
  - For example - pay-checks can be calculated from the time cards, or a summary of sales for the month can be calculated from the sales orders.
- **Output step** – the result of the proceeding processing step is collected.
  - The particular form of the output data depends on the use of the data.
  - For example - output data may be pay-checks for employees.

Data types and its representation

- In computer science and computer programming, a data type is an attribute of data which tells the compiler or interpreter how the programmer intends to use the data.
- Common data types include:
  - Integers
  - Booleans
  - Characters
  - Floating-point numbers
  - Alphanumeric strings
- A data type constrains the values that an expression, such as a variable or a function, might take.
- This data type defines the operations that can be done on the data, the meaning of the data, and the way values of that type can be stored.

Data types and its representation

- On other hand, for the analysis of data, there are three common types of data types or structures:
  - Structured data
  - Unstructured data
  - Semi-structured data.

Structured Data

- Structured data is data that adheres to a pre-defined data model and is therefore straightforward to analyze and to understand.
- Structured data presented in a tabular format with relationship between the different rows and columns and can be sorted.
- Structured data depends on the existence of a data model
- Data model is a model of data that can be stored, processed and accessed. (example DBMS- database management systems)
- Because of a data model, each field is discrete and can be accesses separately or jointly along with data from other fields.
- This makes structured data extremely powerful: it is possible to quickly aggregate data from various locations in the database.
- Common examples are Excel files or date in databases

Unstructured Data

- Unstructured data does not have a predefined data model or is not organized in a pre-defined manner.
- It is without proper formatting and alignment
- Unstructured information is typically text-heavy, but may contain data such as dates, numbers, and facts as well.
- This results in irregularities and ambiguities that make it difficult to understand using traditional programs as compared to data stored in structured databases.
- The ability to analyze unstructured data is especially relevant in the context of Big Data, since a large part of data in organizations is unstructured.
- The ability to extract value from unstructured data is one of main drivers behind the quick growth of Big Data.
- Common examples include: audio, video files or No-SQL databases,

Semi-structured Data

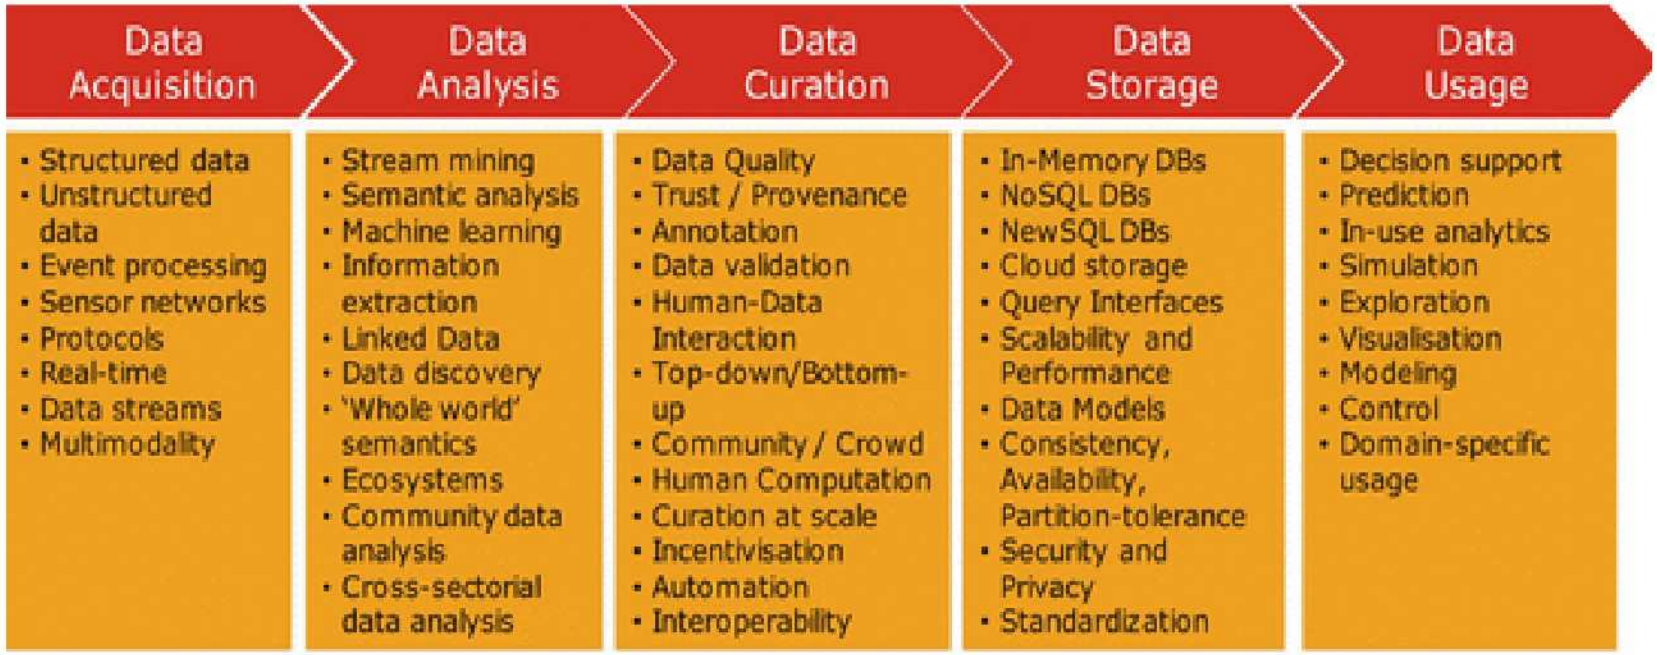
- Semi-structured data is a form of structured data that does not conform with the formal structure of data models (database) or other forms of data tables
- Contain tags or other markers to separate semantic elements and enforce hierarchies of records and fields within the data. Therefore, it is also known as self-describing structure.
- The reason that this third category exists (between structured and unstructured data) is because semi-structured data is considerably easier to analyze than unstructured data.
- Common examples semi-structured data include: emails data, word format, pdf, XML

Metadata - Data about Data

- Metadata is the most important element for Big Data analysis and big data solutions.
- Metadata is data about data.
- It provides additional information about a specific set of data.
- In a set of photographs, for example, metadata could describe when and where the photos were taken. The metadata then provides fields for dates and locations which, by themselves, can be considered structured data.
- Because of this reason, metadata is frequently used by Big Data solutions for initial analysis.

Data Value Chain (DVC)

- The Data Value Chain describes the information flow within a big data system that aims to generate values and useful insights from data. The Big Data Value Chain identifies the following key high-level activities:



Data Acquisition

- It is the process of gathering, filtering, and cleaning data before it is put in a data warehouse or any other storage solution on which data analysis can be carried out.
- Data acquisition is one of the major big data challenges in terms of infrastructure requirements.
- The infrastructure required to support the acquisition of big data must deliver low latency in both capturing data and in executing queries.
- The infrastructure should handle very high volumes of transaction, often in a distributed environment; and support flexible and dynamic data structures

Data Analysis

- It is concerned with making the raw data acquired tc in decision-making as well as domain-specific usage.
- Data analysis involves exploring, transforming, and modelling data
- The goal of data analysis is emphasizing relevant data, synthesizing and extracting useful hidden information with high potential from a business point of view.
- Related areas include data mining, business intelligence, and machine learning.

Data Curation

- It is the active management of data over its life cycle to ensure it meets the necessary data quality requirements for its effective usage.
- Data curation processes can be categorized into different activities such as Content creation, Selection, Classification, transformation, validation and preservation
- Data curation is performed by expert curators that are responsible for improving the accessibility and quality of data.
- Data curators (scientific curators, or data annotators) hold the responsibility of ensuring that data are trustworthy, discoverable, accessible, reusable, and fit their purpose.

Data Storage

- It is the persistence and management of data in a scalable way that satisfies the needs of applications that require fast access to the data.
- Relational Database Management Systems (RDBMS) have been the main and almost unique solution to data storage
- NoSQL technologies have been designed with the scalability goal in mind and present a wide range of solutions based on alternative data models.

Data Usage

- Data usage covers the data-driven business activities that need access to data, its analysis, and the tools needed to integrate the data analysis within the business activity.
- Data usage helps business for decision-making
- Data usage enhances competitiveness through reduction of costs, increased added value, or any other parameter that can be measured against existing performance criteria

Basic Concepts of Big Data

What Is Big Data?

- An exact definition of "big data" is difficult to nail down because projects, vendors, experts, and business professionals use it quite differently. With that in mind, generally speaking, big data is:
  1. Large datasets
  2. the category of computing strategies and technologies that are used to handle large datasets
- "Large dataset" means a dataset too large to reasonably process or store with traditional tooling or on a single computer. This means that the common scale of big datasets is constantly shifting and may vary significantly from organization to organization.
- Big data is a technology needed to gather, organize, and process, insights from large datasets.

Why Are Big Data Systems Different?

- The basic requirements for working with big data are the same as the requirements for working with datasets of any size.
- However, the massive scale, the speed of ingesting and processing, and the characteristics of the data that must be dealt with at each stage of the process present significant new challenges when designing solutions.
- The goal of most big data systems is to surface insights and connections from large volumes of heterogeneous data that would not be possible using conventional methods.
- In 2001, Gartner's Doug Laney first presented what became known as the "three **V**s of big data" to describe some of the characteristics that make big data different from other data processing:

Characteristics of Big Data - 3V's

Volume

- The scale of the information processed helps to define the big data systems.
- These datasets can be orders of magnitude larger than traditional datasets, which demands more thought at each stage of the processing and storage life cycle.
- Often, because the work requirements exceed the capabilities of a single computer, this becomes a challenge of allocating, and coordinating resources from groups of computers.
- Cluster management and algorithms capable of breaking tasks into smaller pieces become increasingly important.

Characteristics of Big Data - 3V's

Velocity

- Big data differs significantly from other data systems is the speed that information moves through the system.
- Data is frequently flowing into the system from multiple sources and is often expected to be processed in real time to gain insights and update the current understanding of the system.
- Data is constantly being added, massaged, processed, and analyzed in order to keep up with the arrival of new information and to surface valuable information early when it is most relevant.
- These ideas require robust systems with highly available components to guard against failures along the data pipeline.

Variety

- Big data problems are often unique because of the wide range of both the sources being processed and their relative quality.
- Data can be ingested from internal systems like application and server logs, from social media feeds, from physical device sensors, and from other providers.
- Big data seeks to handle potentially useful data regardless of where it's coming from by consolidating all information into a single system.
- The formats and types of media can vary significantly as well. Rich media like images, video files, and audio recordings are ingested alongside text files, structured logs, etc.
- While more traditional data processing systems might expect data to enter the pipeline already labeled, formatted, and organized, big data systems usually accept and store data closer to its raw state.

Other Characteristics of Big data - 6V's

- individuals and organizations have suggested expanding the original 3Vs, which tended to describe challenges rather than qualities of big data. The additions include:
- **Veracity**: The variety of sources and the complexity of the processing can lead to challenges in evaluating the quality of the data
- **Variability**: Variation in the data leads to wide variation in quality.
  - Additional resources may be needed to identify, process, or filter low quality data to make it more useful.
- **Value**: The ultimate challenge of big data is delivering value. Sometimes, the systems and processes in place are complex enough that using the data and extracting actual value can become

Big Data Life Cycle

- So how is data actually processed with a big data system?
- The general categories of activities or steps involved with big data processing are:
  I. Ingesting data into the system
  II. Persisting the data in storage
  III. Computing and analyzing data
  IV. Visualizing the results
- Clustered computing - an important strategy employed by most big data solutions is important.

Clustered Computing

- Setting up a computing cluster is often the foundation for technology used in each of the life cycle stages.
- Because of the quantities of big data, individual computers are often inadequate for handling the data at most stages.
- Therefore, to address the high storage and computational needs of big data, computer clusters are a better fit.
- Big data clustering software combines the resources of many smaller machines, to provide a number of benefits:
  - Resource Pooling
  - High Availability
  - Easy Scalability

Clustered Computing

- **Resource Pooling**: Combining the available storage space to hold data is a clear benefit, but CPU and memory pooling is also extremely important. Processing large datasets requires large amounts these three resources.
- **High Availability**: Clusters can provide varying levels of fault tolerance and availability guarantees to prevent hardware or software failures from affecting access to data and processing in real-time analytics.
- **Easy Scalability**: Clusters make it easy to scale horizontally by adding additional machines to the group. This means the system can react to changes in resource requirements without expanding the physical resources on a machine.

Step 1: Ingesting Data into the System

- Data ingestion is the process of taking raw data and adding it to the system.
- Complexity of this operation depends on the format and quality of the data sources and how far the data is from the desired state prior to processing.
- Dedicated ingestion tools that can add data to a big data system are.
  - **Apache Sqoop** - technologies that can take existing data from relational databases and add it to a big data system.
  - **Apache Flume and Apache Chukwa** are projects designed to aggregate and import application and server logs.
  - **Apache Kafka** used as an interface between various data generators and a big data system.
  - **Gobblin** can help to aggregate and normalize the output of these tools at the end of the ingestion pipeline.

Step 1: Ingesting Data into the System

- In the ingestion process - some level of analysis, sorting, and labelling usually takes place.(This process is sometimes called ETL stands for extract, transform, and load).
- Other operations might include modifying the incoming data to format it, categorizing and labelling data, filtering out unneeded or bad data, or validating that it adheres to certain requirements.
- With those capabilities in mind, the captured data should be kept as raw as possible for greater flexibility further on down the pipeline.

Step 2: Persisting the Data in Storage

- The ingestion processes put the data to the disks that manage storages.
- The volume of incoming data, and the requirements for availability make complex storage systems necessary.
- Persisting means leveraging a distributed file system for raw data storage.
  - Persisting tools include: **Ceph and GlusterFS, Apache Hadoop's HDFS** file system allow large quantities of data to be written across multiple nodes in the cluster.

Step 2: Persisting the Data in Storage

- Persisting the Data in Storage ensures:
  - data can be accessed by computer resources
  - Data can be loaded into the cluster's RAM for in-memory operation
  - can handle component failures.
  - Data can also be imported into other distributed systems for more structured access.
- Distributed databases, especially NoSQL databases, are well-suited for this role because they are often designed with the same fault tolerant considerations and can handle heterogeneous data.

Step 3: Computing and Analyzing Data

- Once the data is available, the system can begin processing the data to surface actual information.
- Data is often processed repeatedly - either iteratively by a single tool or by using a number of tools to surface different types of insights.
- Two main method of processing:
  - Batch Processing
  - Real-time processing

Step 3: Computing and Analyzing Data

Batch processing is one method of computing over a large dataset.

- The process involves: breaking work up into smaller pieces, scheduling each piece on an individual machine, reorganizing the data based on the intermediate results, and then calculating and assembling the final result.
- These steps are often referred: splitting, mapping, shuffling, reducing, and assembling, or collectively as a distributed map reduce algorithm. This is the strategy used by Apache Hadoop's MapReduce.
- Batch processing is most useful when dealing with very large datasets that require quite a bit of computation.

Real-time processing

- Real-time processing demands that information be processed and made ready immediately and requires the system to react as new information becomes available.
- stream processing, which operates on a continuous stream of data composed of individual items.
- real-time processor is in-memory computing, which works with representations of the data in the cluster's memory to avoid having to write back to disk.
- **Apache Storm**, **Apache Flink**, and **Apache Spark** provide different ways of achieving real-time or near real-time processing.
- In general, real-time processing is best suited for analyzing smaller chunks of data that are changing or being added to the system rapidly.

Step 4: Visualizing the Results

- Visualizing data is one of the most useful ways to spot trends and make sense of a large number of data points.
- Real-time processing is frequently used to visualize application and server metrics
- The data changes frequently indicate significant impacts on the health of the systems or organization.
  - **Prometheus** can be useful for processing the data streams as a time-series database and visualizing that information.
  - **Elastic Stack** - is one popular way of visualizing data
  - Composed of **Logstash** for data collection, **Elasticsearch** for indexing data, and **Kibana** for visualization, the **Elastic stack** can be used with big data systems to visually interface with the results of calculations or raw metrics.
  - **Apache Solr** for indexing and a **Kibana fork** called Banana for visualization. The stack created by these is called Silk.
  - visualization technology typically used for interactive data science work is a data "notebook".
- These projects allow for interactive exploration and visualization of the data in a format conducive to sharing, presenting, or collaborating.
- Popular examples of this type of visualization interface are Jupyter Notebook and Apache Zeppelin.
